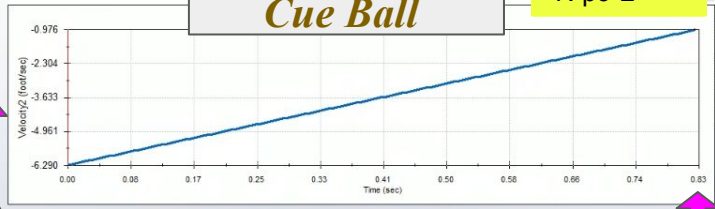
Graphs of Cue Ball

Efe Yamak
2917
N p9-2

The distance between cue ball and the start of "Efe" is 3 ft. That is the line where I took reference as hitting the ball.

0.976 ft/s



The ball's final velocity at t=0.826 s

The initial angular velocity, that was hand calculated, was 142 rad/s (1356 deg/s as shown with a 6.2917 ft/s initial velocity on the x-axis, going in the -x direction.

The goal of this simulation is to prove my hand calculations for the initial velocity of the cue ball and the initial angular velocity of the shield. The angular velocity of the cue ball is in x direction where the angular velocity of the cue ball is in the z direction turning clockwise if we consider positive x axis as going to right and positive y axis as going up where positive z axis is out the screen as shown in the left corner.
